

EXPERIMENT

Build an Electrical Circuit

In order for electricity to travel to where we need it, there must be a complete circuit of electricity. A complete circuit is like a circle. Electricity is produced at one place, travels around the circuit, and returns to the starting place.

Electricity that is produced in power plant generators travels along a circuit. The circuit goes from the generator to homes and businesses and back to the generator. You can build an electrical circuit of your own, using a battery as the electricity source instead of a power plant generator.

Ask an adult to help you with this experiment. Print the page before you start.

Materials

- A printed copy of this activity
- A pencil to write your answers
- 2 pieces of insulated wire with
 1 inch stripped on each end

- Masking tape
- D-cell battery
- A 1.2-volt light bulb with matching base

Directions and Observations

1. Predict what will happen if you build a complete circuit from the battery to the light bulb and back	
again. Write down your prediction before you continue to step 2. My prediction is	

- 2. Use masking tape to connect one end of each wire to the light bulb base.
- **3.** Tape one free wire end to each end of the battery. Was your prediction under step 1 correct? Circle YES or NO. If you circled NO, explain what was wrong with your prediction.

Going Further

- 1. Predict what would happen if you added 10 or more light bulbs to this circuit. My prediction is
- **2.** Watch as your teacher sets up a circuit with one battery and 11 light bulbs. Was your prediction under step 1 correct? Circle YES or NO. If you circled NO, explain what was wrong with your prediction.
- **3.** Suppose you wanted to build a circuit with 24 light bulbs. What adjustments would you have to make to be sure that all the bulbs would light up?
